1 INTRODUCTION

The standard approach to quantify nucleic acids has been the quantitative real-time PCR (qPCR) so far. It is a well established and robist technology which allows precise quantification of DNA material in high throughput fashion at a reasonable price. However the quantification by qPCR is challenging at very low and very high concentrations. At low concentration Monte Carlo effect play a major role and at high concentration inhibition process start to dominate the qPCR. Thus the qPCR is only usable in the working range of the calibrator. Since approximately ten year the digital PCR (dPCR) is gaining entrance in the mainstream user-base. There is currently an intensive research on qPCR platforms with the overall aim to make to technology broadly usable, cheap, robust and to enable high sample throughput. The chemical basis of the dPCR is identical to the qPCR which includes master-mix preparation and thermal cycling of the sample. However, in contrast to qPCR the amplification ration does not take place in a single reaction chamber but is rather a process of clonal amplification in small separate compartments (e.g., nl volume droplets of water oil emulsions, chambers on micro structured chips). The quantification of the amplification is not done by determining a Cq-value derived from an amplification curve but but applying a Poisson distribution based determination of the concentration of the starting material. Therefore the dPCR does not require an external calibration.

qPCR dPCR Number of copies/DNA per volume (e.g., ng/l, copies/l) total number of compartments * ln (...)

A first proposal for digital PCR like approach and the use of the Poisson distribution to quantify the number of molecules on a sample was shown by Ruano et al. 1990 (PNAS) with the single molecule dilution (SMD) PCR. In 1999 Vogelstein et al. (PNAS) described the first true digital PCR. Application of the dPCR cover all applications of conventional qPCR, including investigation of alleles, gene expression analysis and absolute quantification of PCR products. For absolute quantification the qPCR relied on an external calibrator (calibration curve) which was derived serial decadic dilution (e.g., 1:10 1:100 1:1000) of a known target input quantity. The real-time monitoring of the PCR product formation enabled to determine quantification points (Cq). The Cq are strictly related to the input quantity. A simple arithmetic operation (after logarithmic transformation of the concentration) is sufficient to determine any nucleic acid quantity.

The dPCR has some principle assumptions and fundamental properties. First of all the chemical reaction should be not affected by inhibitors. The distribution of the single molecule target regions follows a Poisson distribution. The Poisson distribution appears like a normal distribution but without negative values and being zero the lowest. First a large number (n) of amplifications reactions as required to have a high statistical power. Therefore in practical terms a massive number of PCR reactions is needed. For Poission distributions an n of XY (get reference from table/text book form statistics/biostatistics?) is considered large. Second that the molecules required for the amplification amplifications reactions are randomly distributed in the compartments. Visual analysis, Ripley's K functions or ??? can be used to test for randomness of the reaction and thus to exclude the clustering of of positive reactions. A clustering of positive wells might be due to sample loading or analysis process (systematical error). The outcome of an amplification can be no amplification at all (less than 1 copy per volume), an unsaturated reaction with a binary/multinary amplification (usable to calculate the concentration) or a saturated reaction where virtually all compartments are positive.

Calculation of the Concentration Reference to Supplement

Calculation of the uncertainty To determine the uncertainty of the calculations two approach have been proposed in the peer-review literature (Dube 2008, PLoS One, Bath). The uncertainty is dependent on the number of PCR reactions (reference to dpcR functions). Reference to Supplement and dpcR functions.

Aim of the study We developed the dpcR package which is software suite for analysis of dPCR based on the open source statistical software R. The dpcR includes to invitation to the scientific community to join and support the development of dpcR (github?). The aim of the software is to provide the scientific community a tool

*to whom correspondence should be addressed

for teaching purposes, data analysis, theoretical research (simulation) and to accelerate the development of new approaches to dPCR. We implemented all existing statistical methods for dPCR and suggest the introduction of a standardized nomenclature for qPCR. The package enables the simulations and predictions of Poisson distribution for dPCR scenarios, the analysis of previously run dPCRs.

Interactive use and graphical representation with shiny.

Import and export of results figures and data.

There are currently two technical approaches to dPCR. dPCRs may use (microfluidic)chambers (e.g., QuantStudio 12K Flex (Life Technologies), BioMarkTM EP1TM (Fluidigm)) or emulsion based chambers (QX100TM (Bio-Rad), RainDropTM System (RainDance)). Chamber based dPCR systems have fixed geometries, including the volume of the reaction chambers. Despite the fact that dPCRs is an endpoint analysis the chamber based technologies allow generally the real-time monitoring of the amplification reaction and subsequent confirmation of the amplification reaction be melting curve analysis. Thus, such technologies enable easier trouble shooting and quality management of the data. However, the downside of these technologies is the fixed limited number of compartments and the price. The emulsion based dPCRs are easier to perform since the compartments are generated by microfluidic technologies and have practically no limitation regarding the number of compartments. This results in a higher statistical power to quantify small differences in sample quantities. The emulsion chambers are made of water-in-oil emulsions with similar sizes.

We have chosen R because it is the lingua franca in biostatistics and broadly used in other disciplines. The are many packages in existence which enable the fast development of new methods and plotting facilities.

The packages include MASS, minpack.lm, pracma, qpcR, rgl, robustbase, shiny.

R has a rich set of tool to arrange data (reshape?) in order to prepare them for the analysis. This is important when it comes to the question how experiments should be treated. It is possible to analyze the PCR reaction the panels independently (effect on CI and uncertainty) or to pool/aggregate all reactions (effect on CI and uncertainty) to achieve higher sensitivity/certainty.
